### **BACKGROUND & PURPOSE**

There is a great unmet need for the development of effective treatments to treat the symptoms of OA. Low-grade inflammation in OA has been highlighted as a major driver for disease. The Nuclear-Factor Kappa-B (NF-kB) pathway mediates an array of inflammatory and tissue degrading processes with increased release of extra-cellular matrix fragments activating additional inflammatory cascades and is involved in OA pathogenesis. Nrf2 is a nuclear transcription factor that plays a key role in response to oxidative stress and has also been demonstrated to play a role in OA pathogenesis. A fixed-dose combination of apocynin and paenol in a ratio of 2:7 (APPA) has been shown to inhibit activation of NF-κB cascade, reducing inflammation and upregulating Nrf2, and reducing damage caused by reactive oxygen species(1). We report the results of a phase 2a study evaluating the efficacy and safety of APPA in patients with symptomatic knee OA.

#### **METHODS** DESIGN

The trial was a 28-day randomized, placebo-controlled, double-blind study comparing 800 mg of APPA twice daily with matched placebo capsules. The primary endpoint was change from baseline to Day 28 in the WOMAC pain score. Key secondary endpoints included WOMAC Function, Stiffness and Total scores. Safety outcomes included reported adverse events (AE), clinical laboratory parameters, ECG, and vital signs. A pre-defined subgroup analysis in subjects with a baseline PainDETEC1 score >12 indicated a positive effect. Accordingly, post-hoc analyses were undertaken to further assess the effects of APPA in subgroups of participants with higher disease severity. The trial design is illustrated below in Figure 1.

## PARTICIPANTS

Patients with radiographic knee OA KL-grade 2 or 3, and a WOMAC pain score ≥40 and ≤90/100 of target knee at screening and baseline were randomized 1:1 to APPA or placebo. Main exclusion criteria included recent intraarticular surgery or injection therapy, hip pain greater than the target knee, and BMI  $\geq$ 40 kg/m<sup>2</sup>.

### **STATISTICS**

Treatment effect of the primary endpoint was based on a repeated measures mixed model including the terms of sex, center, characteristics of unilateral/bilateral knee OA, visit, treatment, baseline score as covariates, and treatment by visit interaction. An AR(1) covariance structure was used to model the correlations between within-subject repeated measurements. Comparison of APPA versus placebo was performed within the context of this model. The same mixed model used for the primary endpoint was used to assess the treatment effect of the main secondary endpoints. The significance level was set at 5 % two-sided.

One-hundred and fifty-two participants were randomized, and 149 (98%) completed the trial. The study population was well balanced between the treatment groups, as shown in Table 1.

The primary endpoint of change in WOMAC pain from baseline to Day 28 was not met, mean difference between APPA and placebo was -0.89 (95 % CI: -5.62, 3.84, p=0.71, Figure 2). Similarly, no significant differences were found on other secondary endpoints as shown in Figure 3)

## **RESULTS - SUBGROUP ANALYSES**

A pre-defined subgroup analysis in subjects with a baseline PainDETECT score >12 indicated a positive effect. Accordingly, post-hoc analyses were undertaken to further assess the effects of APPA in subgroups of participants with higher disease severity. Figure 4 shows the PainDETECT-subgroup, and the analysis of participants > 50 WOMAC pain at baseline (Group 1, N=95), and a KL-grade of the nontarget knee >2 (Group 2, N=105), and a combination of these two criteria (Group 3, N=64).

As illustrated above, a positive effect of APPA compared to placebo was observed (Group 1 mean difference: -2.61, 95 % CI: -8.98 to 3.76, p=0.42, Group 2 mean difference: -4.01, 95 % CI: -9.35 to 1.33, p=0.14, and Group 3 mean difference -8.32, 95 % CI: -15.48 to -1.16, p=0.02).

exploratory The (Figure subgroups 5) suggest that OA subjects with higher symptomatic severity, and disease potential involvement of reflected in processes possible neuropathic changes and/or highly inflammatory-driven OA might benefit trom APPA.

## **SAFETY**

At least one adverse event was reported by 36.0 % and 41.6 % of study participants receiving APPA or placebo, respectively. APPA was well tolerated and as shown in Table 2, no differences in frequencies of reported AEs were noted, apart from a higher proportion of subjects reporting gastrointestinal discomfort reported with APPA compared to placebo. All but one reported AEs were mild to moderate. In total, three participants discontinued the trial; two in the APPA group, and one receiving placebo.

One AE, "diarrhoea" in a participant receiving APPA led to discontinuation from the trial. During the trial one serious adverse event (prostate cancer) was reported, in a participant receiving placebo.

No clinically relevant changes were found on clinical biochemistry or hematology parameters, urine dipstick, vital signs nor ECG parameters.

<b>Table 2</b> : Treatment-emergent adverse events reported with a frequency of > 2 % in either treatment group.			
Safety population System Organ Class Preferred Term	APPA N=75 n (%), E	Placebo N=77

## **CONCLUSION**

Treatment with APPA 800 mg twice daily for 28 days in patients with symptomatic knee OA was not overall associated with significantly improved outcomes compared to placebo. The treatment was well-tolerated and safe. Exploratory subgroup analyses, however, showed a significant effect of APPA in patients with moderate to severe OA indicating that further research in the effects of APPA in appropriate patients is warranted.

## PERSPECTIVES

- OA patients with higher inflammatory involvement may experience higher symptom severity
- The findings that APPA may be more efficacious in OA patients with higher symptom severity may reflect anti-inflammatory effects by APPA
- Future research should evaluate the effect of APPA in OA patients with inflammatorydriven disease
